AI IMPACT ON
JOB (RESEARCH
QUESTIONS)

Research / Analysis Questions:

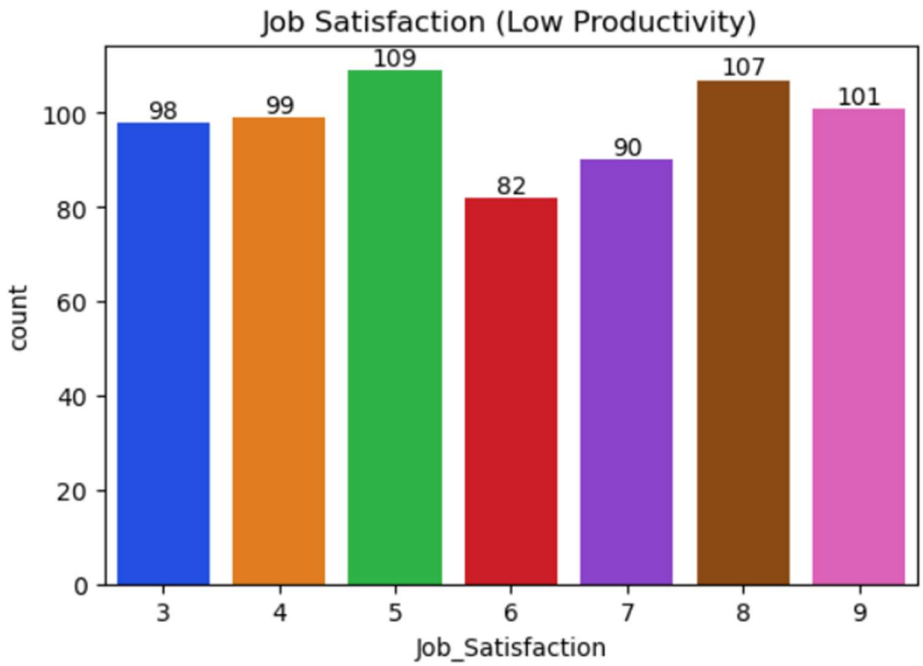
- How can we support employees whose productivity has decreased to improve their performance?
- Which groups of employees show low job satisfaction, and what specific issues are affecting them?
- What practices are followed by employees with higher productivity, and how can these be applied across teams?
- Are employees working longer hours actually more productive, or is there a point where performance drops?
- How does remote vs office work affect employee productivity and satisfaction, and which setup works better for different roles?

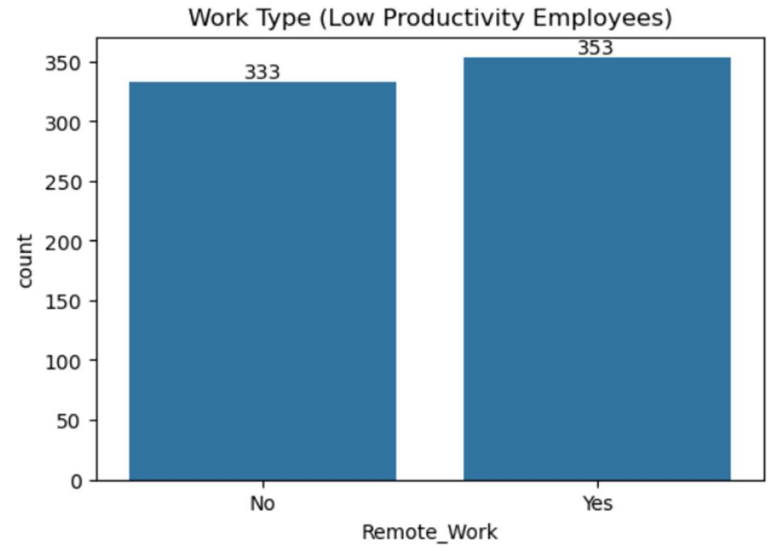
- Which departments or roles are at higher risk of job changes, and how can we prepare those employees for future responsibilities?
- What factors are helping some employees adapt better to new tools, while others are struggling?
- Is there a connection between balanced work hours and stable performance, and how can we maintain that balance?
- How can managers better support employees to improve both satisfaction and productivity at the same time?
- What steps can the company take to create a more adaptable workforce that can handle future changes in the job environment?

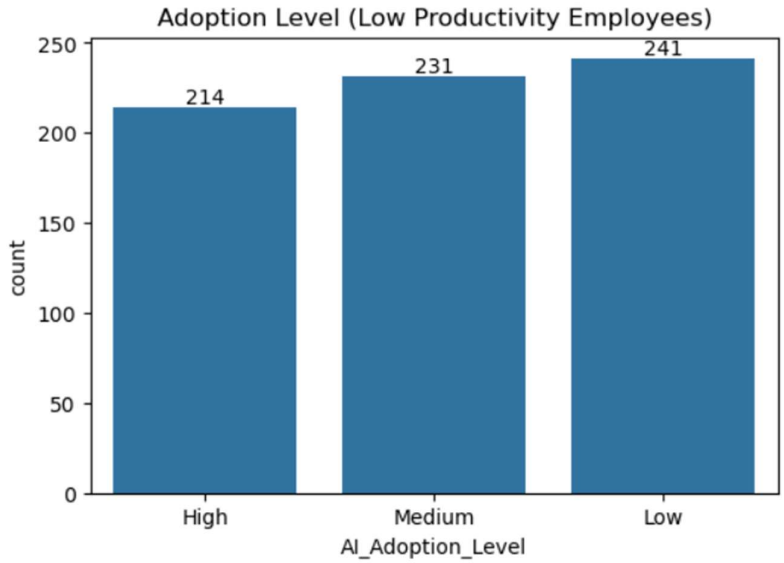
Q1: **How can we support employees whose productivity has decreased to improve their performance?**

For this first of all we filter the employes with decreased productivity, then check their characteristics such as (work hours, Ai adoption level, job satisfaction, work type(remote yes/no))

THE NUMBER OF EMPLOYEES WITH PRODUCTIVITY DECREASED ARE: 686







Conclusion:

The decrease in productivity is not driven by a single factor such as job satisfaction, work type, or adoption level, as these are evenly distributed among employees. However, work hours appear slightly higher, suggesting that workload and fatigue may be contributing factors to reduced productivity.

Q2: Which groups of employees show low job satisfaction, and what specific issues are affecting them?

This Question is linked to question 1:

Analytical statement

- There is no single group of employees responsible for low productivity, as it is distributed across all categories. However, slightly higher work hours may be one of the contributing factors.
- Since productivity decline is not limited to any specific group, the issue appears to be more general, with workload being a potential influencing factor rather than a sole cause.

Q3:What practices are followed by employees with higher productivity, and how can these be applied across teams?

Filter the employees with high productivity and then analyze their traits such as work hours, job satisfaction, work type, ai _adoption level

TOTAL EMPLOYEES WITH HIGH PRODUCTIVTY:1023

Conclusion:

- Higher productivity is strongly associated with greater adoption of tools, while factors like job satisfaction and work location show no significant impact. Additionally, high-performing employees tend to maintain balanced working hours, indicating that efficient work practices are more important than longer working hours.Employees who use

tools more and maintain balanced work hours tend to be more productive.

- Productivity improves with better tool usage and balanced workload, not by increasing working hours

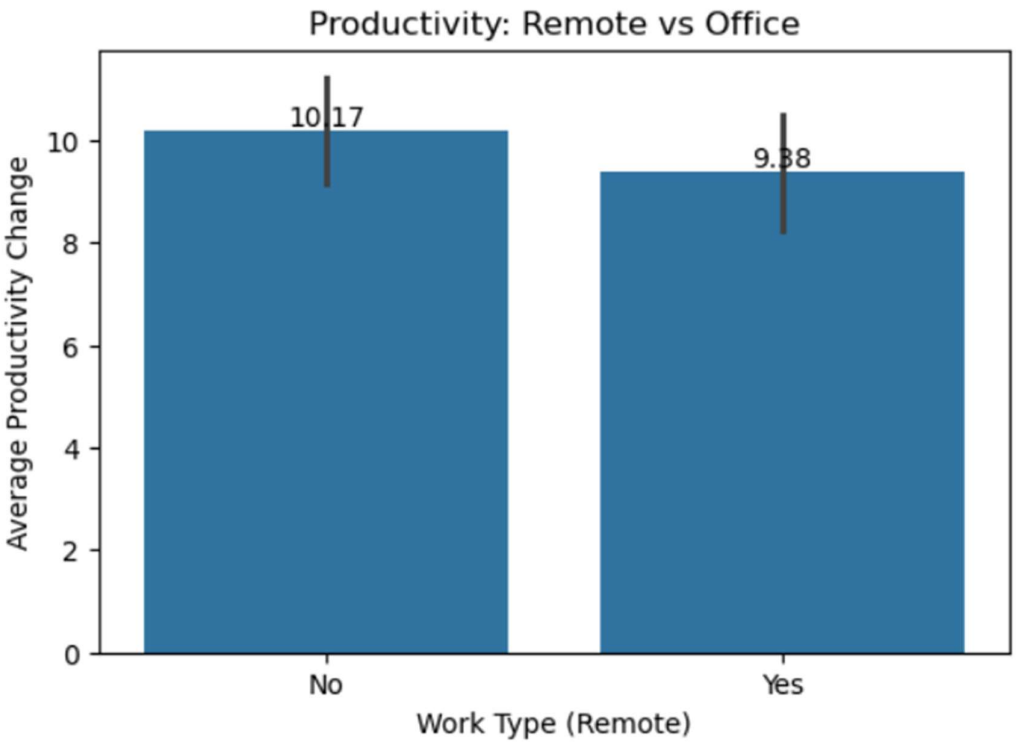
Q4:Are employees working longer hours actually more productive, or is there a point where performance drops?

Conclusion:

As we have seen in previous analysis:

Employees working longer hours are not necessarily more productive. The data shows that both high and low productivity employees have similar working hours. There is no clear evidence that increasing work hours improves performance. This suggests that productivity depends more on factors like skills, tools and work efficiency rather than just time spent working.Longer working hours do not guarantee higher productivity.

Q5:How does remote vs office work affect employee productivity and satisfaction, and which setup works better for different roles?



Productivity: Remote vs Office

4
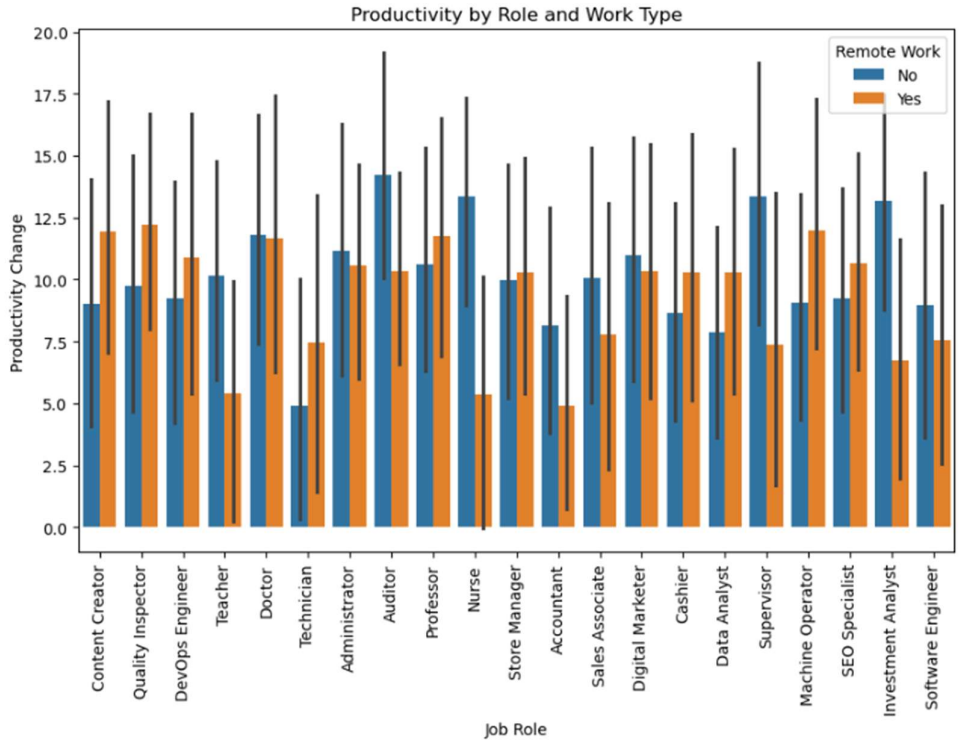
5
6
No
Yes
Work Type (Remote)



Conclusion:

Office-based employees show slightly higher productivity (10.17%) compared to remote employees (9.38%), while job satisfaction remains almost the same in both setups (around 6.0). This indicates that work location has a minor impact on productivity and no significant impact on satisfaction.

At the role level, there is no consistent pattern where remote or office work is always better. Some roles perform slightly better in office settings, while others show similar performance in both. This suggests that the effectiveness of remote work depends on the nature of the job rather than a single general rule.

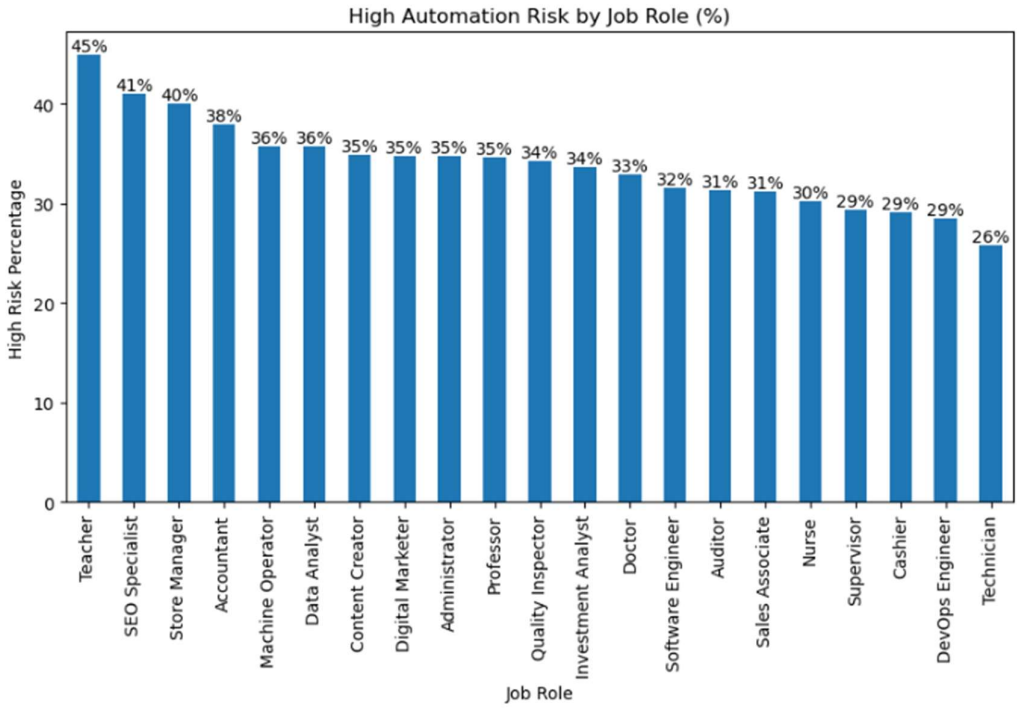
Overall, work location alone does not strongly determine employee performance. Factors like work efficiency, tools, and

role requirements play a more important role than whether employees work remotely or in the office.

One line answer:

Work setup has a limited impact on performance; the role and work efficiency matter more

Q6:Which departments or roles are at higher risk of job changes, and how can we prepare those employees for future responsibilities?



Conclusion:

- Risk is higher in roles with repetitive and predictable tasks, while roles requiring human judgment, creativity, and decision-making show relatively lower risk.
- The analysis shows that roles such as Teacher, SEO Specialist, Store Manager, and Accountant have the highest percentage of employees at high risk, indicating a greater likelihood of job changes. These roles often involve structured and repetitive tasks. Roles with medium risk present a strong opportunity for transition, as employees in these positions can adapt with the right training. To prepare employees for future responsibilities, organizations should focus on skill development, encourage the use of modern tools, and shift employees toward more analytical and decision-based work. This will help reduce risk and improve long-term performance.

Q7:What factors are helping some employees adapt better to new tools, while others are struggling?

With the help of previous analysis

Conclusion:

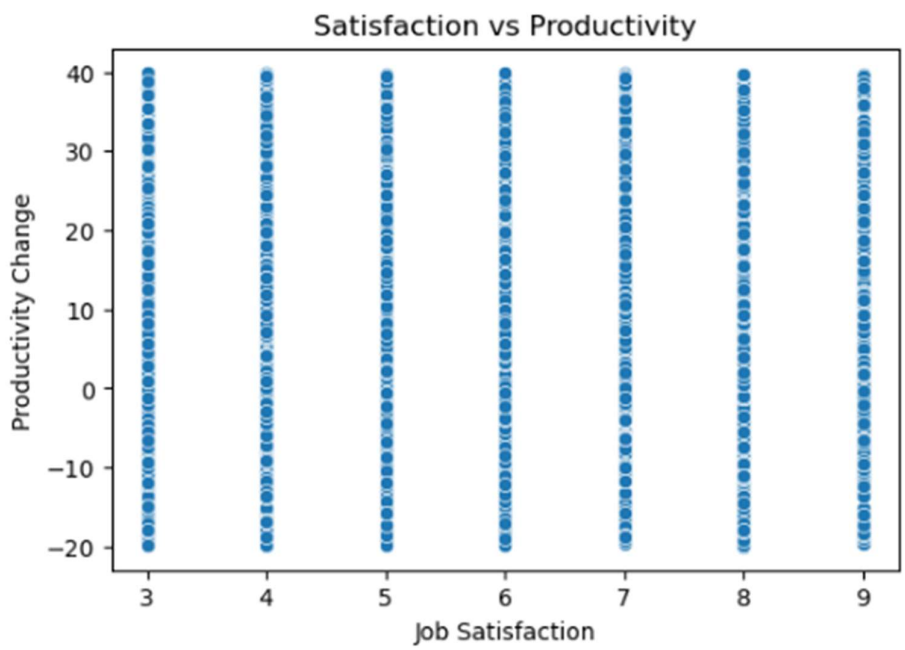
Employees who are adapting better are not just using tools more; they are more open to change, work more efficiently, and are often in roles that support tool usage. In contrast, employees who are struggling are usually in repetitive roles, show lower adoption levels, and rely more on traditional work methods.

Q8:Is there a connection between balanced work hours and stable performance, and how can we maintain that balance?

Conclusion:

There is no strong connection between longer work hours and higher productivity. Stable performance is achieved through balanced workloads and efficient work practices rather than increased working time.

Q9:How can managers better support employees to improve both satisfaction and productivity at the same time?



```
df[['Job_Satisfaction', 'Productivity_Change_%']].corr()
```

	Job_Satisfaction	Productivity_Change_%
Job_Satisfaction	1.000000	-0.014112
Productivity_Change_%	-0.014112	1.000000

Conclusion:¶

Productivity is driven more by efficiency, skills, and tool usage than by satisfaction, work hours, or location.

Q10:What steps can the company take to create a more adaptable workforce that can handle future changes in the job environment?

Conclusion:

To build an adaptable workforce, companies should focus on skill development, effective use of tools, and shifting employees toward more analytical roles. Balanced workloads and flexible work environments further support long-term adaptability.

Business Recommendations:

- Focus on **skill development and training programs**
- Encourage **effective use of modern tools**
- Shift employees from **repetitive tasks to analytical roles**
- Maintain **balanced workloads**
- Provide **flexible work environments**
- Support a culture of **continuous learning**

Final & Overall Conclusion:

The future of work depends on how well employees adapt, not on how long they work or where they work.
